## Exercise sheet 7, 12 January 2023

- 1. If the secret shared via Shamir secret sharing is an element in a finite field one can keep shares and Lagrange coefficients small(er) by computing the coefficients in the finite field. Note that this works for secrets in  $\mathbb{Z}/n$  in general, but then care needs to be taken to avoid denominators that are not invertible.
  - Use Shamir's secret sharing to share a=5 modulo 103 in a 3-out-of-5 fashion. Verify for two sets of 3 users that you can recover the secret.
- 2. In Shamir's secret sharing there is a lot of trust on the party S that shares the keys. A malicious S could give invalid shares to some people, so that any group of t people involving at least one of them would compute the wrong secret. To prevent this, all parties insist on S publishing some extra information.
  - Let S publish  $g^a$  and  $g^{f_i}$  for  $1 \le i < t$ , where g is the generator of some large DH group. Show how participant j can verify that his share (j, f(j)) is correct given the information provided by S.
- 3. Let the DH secret a be shared in a t-out-of-N fashion. Show how to compute  $g^{ab}$  given  $g^b$  and the shares, without recomputing a, i.e. using the shares locally.
- 4. Let the RSA secret key d be shared in a t-out-of-N fashion. Show how to do RSA decryption using shares locally, i.e. without recovering the secret d.

Note, this one is much harder than for DH.
