Cryptanalysis

- ▶ Cryptanalysis is the study of security of cryptosystems.
- ▶ Breaking a system can mean that the hardness assumption was not hard or that it just was not as hard as previously assumed.
- ▶ Public cryptanalysis is ultimately constructive – ensure that secure systems get used, not insecure ones.
- ▶ Weakened crypto ultimately backfires – attacks today because of crypto wars in the 90s.
- ▶ Good arsenal of general approaches to cryptanalysis. There are some automated tools.
- ▶ This area is constantly under development; researchers revisit systems continuously.

Security assumptions

- ▶ Hardness assumptions at the basis of all public-key and essentially all symmetric-key systems result from (failed) attempts at breaking systems.
- ▶ Security “proofs” are built only on top of those assumptions. These relate the hardness of breaking a bigger system to the hardness of these assumptions.
- ▶ A solid symmetric system is required to be as strong as exhaustive key search.
- ▶ For public-key systems the best attacks are faster than exhaustive key search. Parameters are chosen to ensure that the best attack is infeasible.

Key size recommendations

	Parameter	Legacy	Future System Use	
			Near Term	Long Term
Symmetric Key Size	k	80	128	256
Hash Function Output Size	m	160	256	512
MAC Output Size*	m	80	128	256
RSA Problem	$\ell(n) \geq$	1024	3072	15360
Finite Field DLP	$\ell(p^n) \geq$	1024	3072	15360
	$\ell(p), \ell(q) \geq$	160	256	512
ECDLP	$\ell(q) \geq$	160	256	512

- ▶ Source: ECRYPT-CSA “[Algorithms, Key Size and Protocols Report](#)”.
- ▶ Recommendations extrapolate from attacks known today.
- ▶ Attacker power typically limited to 2^{128} operations (less for legacy).
- ▶ More to come on long-term security ...

Current state of the art in applied cryptography

- ▶ Currently used crypto (check the lock icon in your browser) starts with RSA (can be broken by factoring large integers), Diffie-Hellman in finite fields, or elliptic-curve Diffie-Hellman (both require the attacker to compute discrete logarithms in some group).
- ▶ Older standards are RSA or elliptic curves from NIST (or Brainpool), e.g. NIST P256 or ECDSA.
- ▶ Internet currently moving over to [Curve25519](#) and [Ed25519](#)
- ▶ For symmetric crypto, TLS (the protocol behind https) uses AES or ChaCha20 and some MAC, e.g. AES-GCM or ChaCha20-Poly1305. High-end devices have support for AES-GCM, smaller ones do better with ChaCha20-Poly1305.
- ▶ Security is getting better. Some obstacles: bugs; untrustworthy hardware.
- ▶ Some countries make ill-advised recommendations to weaken crypto.

Algorithms for Quantum Computation: Discrete Logarithms and Factoring

Abstract

A computer is generally considered to be a universal computational device; i.e., it is believed able to simulate any physical computational device with a cost in computation time of at most a polynomial factor. It is not clear whether this is still true when quantum mechanics is taken into consideration. Several researchers, starting with David Deutsch, have developed models for quantum mechanical computers and have investigated their compu-

[1, 2]. Although he did not ask whether quantum mechanics conferred extra power to computation, he did show that a Turing machine could be simulated by the reversible unitary evolution of a quantum process, which is a necessary prerequisite for quantum computation. Deutsch [9, 10] was the first to give an explicit model of quantum computation. He defined both quantum Turing machines and quantum circuits and investigated some of their properties.

The next part of this paper discusses how quantum computation relates to classical complexity classes. We will

Quantum computing could end encryption within five years, says Google boss

Mr Pichai said a combination of artificial intelligence and quantum would "help us tackle some of the biggest problems we see", but said it was important encryption evolved to match this.

"In a five to ten year time frame, quantum computing will break encryption as we know it today."

This is because current encryption methods, by which information such as texts or passwords is turned into code to make it unreadable, rely upon the fact that classic computers would take billions of years to decipher that code.

- ▶ ~~2021~~ 2022 “~~not later than the end of March~~”: 05 Jul NIST announces first selections.
- ▶ 24 Aug 2023: First draft of 3 NIST post-quantum standards.

Major categories of public-key post-quantum systems

- ▶ **Code-based:** Security relies on hardness of decoding error-correcting codes. Short ciphertexts and large public keys. McEliece system is from 1978.
- ▶ **Hash-based:** Security directly linked to hash function properties.– Very solid security and small public keys.
- ▶ **Isogeny-based:** Security relies on hardness of finding isogenies between elliptic curves over finite fields. Fairly new schemes, but smallest overall.
- ▶ **Lattice-based:** Security relies on hardness of finding short vectors in some (typically special) lattice. Possibility for balanced sizes.
- ▶ **Multivariate-quadratic:** Security relies on hardness of solving systems of multivariate equations. Short signatures and large public keys.

Warning: These are categories of mathematical problems; individual systems may be totally insecure if the problem is not used correctly.

We have good algorithmic abstraction of what quantum computers can do, but new systems need more analysis. Any extra structure offers more attack surface.

Deployment issues & solutions

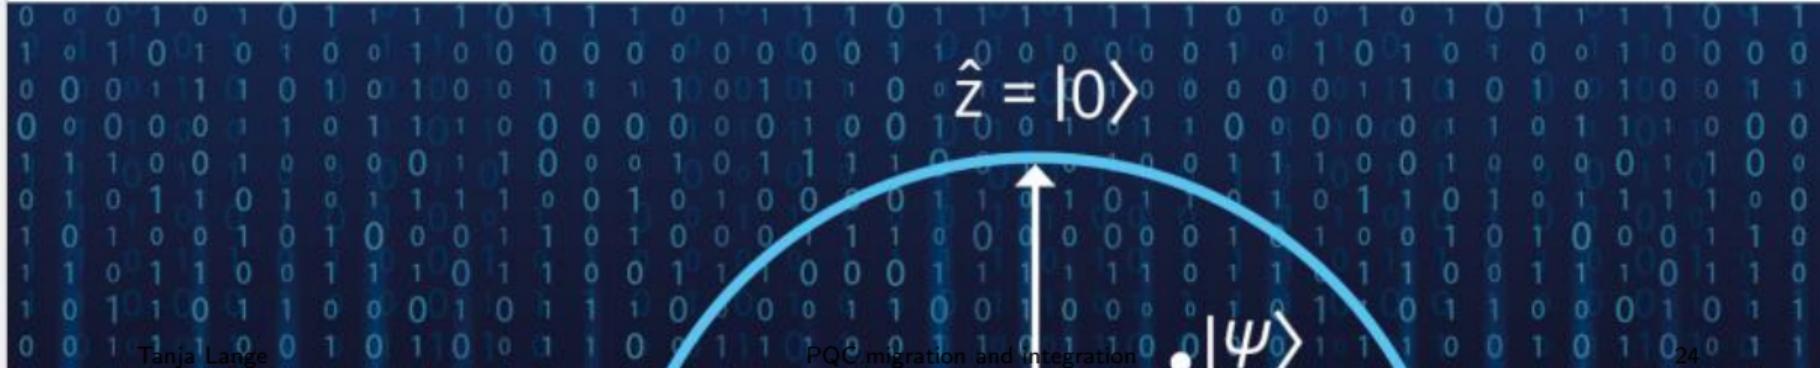

- ▶ Different recommendations for rollout in different risk scenarios:
 - ▶ Use most efficient systems with ECC or RSA, to ease usage and gain familiarity.
 - ▶ Use most conservative systems (possibly with ECC), to ensure that data really remains secure.
- ▶ Protocol integration and implementation problems:
 - ▶ Key sizes or message sizes are larger for post-quantum systems, but IPv6 guarantees only delivery of ≤ 1280 -byte packets, TLS software has length limits, etc.
 - ▶ Google [experimented](#) with larger keys and noticed delays and dropped connections.
 - ▶ Long-term keys require extra care (reaction attacks).
- ▶ Some libraries exist, quality is getting better. item [Google](#) and [Cloudflare](#) are running some experiments of including post-quantum systems into TLS.
